# 1 Overview of exercises (PART I)

1. limb-darkening scattering exercise we did during the course. — You can look into your notes from that, and I attach here also a sample program which you can use a base. After you have familiarised yourself with this, you can start to think bout how you would go about to extend this to a 3D setting (assuming isotropic scattering).

2. (As prep for Monte-Carlo school) here is a script computing a UV resonance P-Cygni line in spherically symmetric wind with v beta-law. At top of routine, a few exercises are given, where you can modify and play around with code. Monte-Carlo program which computes a UV resonance spectral line from a fast outflowing spherically symmetric stellar wind (if you were not cc'd on that email, let me know so that I can send you the files as well). At the top of that little script, there are a few suggestions for exercises (additions) you could do to that program, in order to learn a bit more about the general workings of Monte-Carlo radiative transfer in this context. — So that might be a good idea for you to do as well ! (And you can also ask the others in the group for some tips etc. then.)

3. Some background reading:
   - Attached mc manual by Puls.
   - Paper by Sundqvist+ 2010 (Appendix, I think).

# 2 Overview of exercises (PART II)

1. Calculate the probability distribution to sample from in the case of Eddington limb darkening for the initial distribution (see 4.3.4).

2. Calculate analytical solution for simplified problem in 4.3.2 in the case that `mu = 1`.

3. Perform convergence analysis. See Section 4.3.6

# 3 Limb darkening

### 3.0.1 2D Case

We again have $\mu = \cos(\theta)$. The solution of the radiative transfer equation in <u>plane-parallel syummetry</u> with frequency-independent absorption and emission, is

$$I(\mu) = I_1(0.4 + 0.6\mu) \tag{1}$$

In the Monte Carlo code, the photons are sorted according to the direction that they leave the atmosphere.

**Goal**   Calculates the angular dependence of photon's emitted from a plane-parallel, grey atmosphere of radial optical depth `taumax`. The value of `tau` determines the position of the photon

**Variables and Algorithm**

- `muarray` contains emergent photons

- `na` number of channels

- `dmu` $= 1/$`na` width of channels

- `nphot` number of photons

- `taumax` maximum optical depth

---

**Algorithm 1** Limb darkening: compute quantitiy of photons

---

   initialization
      radial optical depth $\tau$
      direction $\mu$
   **for** all photons **do**
      $\boxed{\tau = \tau_{max}}$
      **while** `tau` $\geq 0$ **do**
         compute scattering angle `mu`
         **if** tau $\geq$ taumax **then** $\boxed{mu = sqrt(x)}$ (initial distribution)
         **else** $\boxed{mu = 2 * x = 1}$ (isotropic scattering)
         tau_i = -log(x2)
         tau = tau - tau_i*mu
      **end while**
      now we know that the photon has left the photosphere
      compute the distribution of all angles `mu` at which the photon left the photosphere
   **end for**
   visualisation:
      - plot photon numbers from $\mu d\mu$ against `mu`
      - plot specific intensity from $d\mu$ against `mu` against

---

   Figure 1 is according to what is expected $I = I_0(0.4 + 0.6\mu)$

Figure 1: histogram for `mu`

### 3.0.2   3D Code

What changes is this:

- introduction of a new angle $\phi$
- the optical depth has to be updated according to $\phi$ also

Figure 2: histogram for `mu`

Figure 3: histogram for `phi`

Figure 2 and Figure 3 are according to what is expected, namely $I = I_0(0.4 + 0.6\mu)$ and a uniform distribution for $phi$, which corresponds to a $I \sim \dfrac{1}{\phi}$

# 4 Investigation of program: pcyg.f90

## 4.1 Overview of variables

| name | explanation |
|---|---|
| paramaters | |
| xk0 | |
| alpha | velocity profile parameter |
| beta | velocity profile parameter |
| start frequency of the photon | |
| xstart | start frequency |
| vmin | |
| vmax | |
| angle of the photon | |
| xmuestart | start angle |
| xmuein | incident angle |
| xmueou | outward angle |
| pstart | impact parameter |
| xnew | new photon frequency |
| optical depth | |
| tau | optical depth |
| number of photons admin | |
| nphot | number of photons |
| nin | photons scattered back into core |
| nout | photons escaped |
| functions | |
| func | velocity profile |
| | distance from center of star $r$ |
| xmueout | outwards (scattered) angle |
| | xk0 |
| | alpha |
| | r |
| | v |
| | sigma |

## 4.2   Mathematical things that are noteworthy

### 4.2.1   General working

The photons are sorted according to `xnew`. In general, the flux is dependent on $\mu$ and the frequency $x$.

| make formula |
| --- |

- I think that it satisfies $N(x)dx \sim I(x)xdx$

- We are thus interested in $F_\lambda = F_\nu$

### 4.2.2   Practical formula

- emission angle $\mu = \cos(\theta)$

- according p-ray $p = \sqrt{1 - \mu^2} = \sin(\theta)$

- incident angle $\texttt{xmuein} = \sqrt{1 - \left(\dfrac{pstart}{r}\right)^2}$

### 4.2.3   Geometry & Symmetry assumptions

- spherical geometry

## 4.3   Exercises

### 4.3.1   Investigation of original code

In original version of the code, all photons are released isotropially from the photosphere.

Figure 4: Original version of the code

### 4.3.2 First adaptation: what if all photons are released radially from photosphere?

**Release photons radially: numerical MC experiments** What would happen with line-profile, if you assumed all photons were released radially from photopshere?

- In other words `xmuestart = 1`. Results in Figure **??**.

- This is implemented under the test case `test_number=1`.

(a) First adaptation

(b) Same plot (together with output of initial version)

Figure 5: The number of photons equals $10^5$

**Derive analytic expression** See also slide 26/49 [Sundqvist course material].

- since `xmuein = 1` we have for the velocity profile

$$v = v_\infty (1 - b/r)^\beta \tag{2}$$

A scaled version of the Equation (2) yields

$$u = \frac{v(r)}{v_\infty} = \left(1 - \frac{r_\infty}{r}\right)^\beta \tag{3}$$

with $u \in [0..1]$

- Doppler shift for the frequency of the photons: $x_{CMF} = x_{REF} - \mu u$.

- Condition for resonance from Sobolov approximation (to be studied later): $\boxed{x_{CMF} = 0}$ thus

$$x_{REF} = \mu u \tag{4}$$

or thus $x_{REF} = \boxed{u_{\text{interaction}}}$ and than solve Equation 3 for $r_{\text{interaction}}$

- If $\mu = 1$ then

$$x = \left(1 - \frac{r_\infty}{r}\right)^\beta \tag{5}$$

$$x^{-\beta} = 1 - \frac{r_\infty}{r}$$

$$r(1 - x^{-\beta}) = r_\infty$$

$$\boxed{r(x) = \frac{r_\infty}{1 - x^{-\beta}}} \tag{6}$$

- From the location of interaction $r$, the incident angle can be calculated

$$\texttt{xmuein} = \sqrt{1 - \left[\frac{\texttt{pstart}}{r}\right]^2} = \sqrt{1 - \left[\frac{\sqrt{1 - \texttt{xmuestart}^2}}{r}\right]^2} \tag{7}$$

Now also taking into account that $\texttt{xmuestart = 1}$ then yields

$$\texttt{xmuein = 1} \tag{8}$$

- The calculation of the optical depth goes as follows:

$$\tau = \frac{\texttt{xk0}}{rv^{2-\alpha}(1 + \texttt{xmuein}^2\sigma)} \tag{9}$$

Now also taking into account that $\texttt{xmuestart = 1}$ gives

$$\tau = \frac{\texttt{xk0}}{rv^2(1 + \sigma)} \tag{10}$$

where $\boxed{v(x) = \left(1 - \dfrac{b}{r}\right)^{\beta}}$ and $\dfrac{dv}{dr} = \dfrac{\beta b}{r^2}\left(1 - \dfrac{b}{r}\right)^{\beta - 1}$

and $\sigma(x) = \dfrac{dv}{dr}\dfrac{r}{v} - 1$ thus $\boxed{\sigma(x) = \dfrac{\beta b}{r}\left(1 - \dfrac{b}{r}\right)^{-1}}$

- Conclusion: $\tau(x)$ is only dependent on $x$ and not on $\texttt{xmuestart}$ or $\texttt{xmuein}$.

- $\texttt{xmueou}$ follows the distribution as given by the function $\texttt{xmueout}$, namely

$$p(x) = \frac{1 - e^{-\tau}}{\tau} \tag{11}$$

with $\tau = \dfrac{\texttt{tau0}}{1 + \texttt{X}^2\sigma}$ where $\texttt{X}$ is a random number, so actually this comes down to

$$\boxed{p(x) = \frac{1 - e^{-\frac{\tau_0}{1 + x^2\sigma(x)}}}{\frac{\tau_0}{1 + x^2\sigma(x)}}} \tag{12}$$

- Finally one can combine these results to get the distribution of the photons according to the frequency $x$ via the relation
$$\texttt{xnew = xstart + v(xmueou-xmuein) = xstart + v(xmueou -1)} \tag{13}$$

Via this link, you can go back to the exercises overview: Section 2.

### 4.3.3 Second adaptation: isotropic scattering

What would happen to line-profile, is you assumed scattering was isotropic
(i.e., NOT following Sobolev-distrobution)

- test case number 2

(a) Second adaptation

(b) Same plot (together with output of initial version)

Figure 6: The number of photons equals $10^5$

The *grosso modo* form has not changed, although the scaling has changed.

### 4.3.4 Third adaptation: introduction of Eddington limb-darkening

Put Eddington limb-darkening in. What happens?

**General (introductory) discussion: Eddington limb darkening** The data are taken from Christensen, 2015.

- the source function $S =<I>= a + b\tau_\nu$ with $a = \dfrac{\sigma}{2\pi}T_{eff}^4$ and $b = \dfrac{3\sigma}{4\pi}T_{eff}^4$

- solve the equation

- this yields $\dfrac{I(\theta)}{I(0)} = \dfrac{a + b\cos(\theta)}{a + b} = \dfrac{2}{5} + \dfrac{3}{5}\cos(\theta)$

Figure 7: Eddington limb darkening (two times the same plot with $\mu = \cos(\theta)$)

**Construction of probability distribution corresponding to Eddington limb darkening**

1. Let us thus first review the emmission case where the flux in each direction is isotropic i.e. $I(\theta) = I$ (as experimented in paragraph 4.3.3)

    - the specific intensity is defined as $I_\nu(\mu) = \dfrac{dE_\nu}{\cos(\theta)dAdtd\nu d\Omega} = \dfrac{dE_\nu}{\mu dAdtd\nu d\Omega}$

    - the flux $F_\nu = \displaystyle\int_\Omega I_\nu \cos(\theta)d\Omega$ is in this case isotropic thus

$$\xi = \int_0^\mu F_\nu d\mu = \int_0^\mu \int_\Omega I_\nu \cos(\theta)d\Omega d\mu = A \int_0^\mu \mu d\mu \tag{14}$$

    together with the condition that $\mu$ satisfies a probability distribution:

$$1 = \int_{-1}^1 F_\nu d\mu = \int_{-1}^1 \int_\Omega I_\nu \cos(\theta)d\Omega d\mu = \dfrac{A}{2} \tag{15}$$

    thus $A = 2$. Photons need to be sampled according to $\mu d\mu$.

2. Now we look at a new case where the photons need to be emitted following a distrubution that corresponds to $I(\theta) = I(0)(0.4 + 0.6\cos(\theta))$.

- in this case the flux $F_\nu = \int_\Omega I_\nu \cos(\theta)d\Omega$ is isotropic but also satisfies

$$F_\nu = \int_\Omega I_\nu(0)[0.4 + 0.6\cos(\theta)]\cos(\theta)d\Omega \tag{16}$$

I am not sure about the correctness of the assumption of isotropy of the flux

$$\xi = \int_0^\mu F_\nu d\mu = A \int_0^\mu (0.4 + 0.6\mu)\mu d\mu \tag{17}$$

subject to the normalisation condition -very similar to Equation (15) - that

$$1 = \int_{-1}^1 F_\nu d\mu = \frac{2A}{5} + \frac{A}{3} = \frac{11A}{15} \tag{18}$$

thus $A = \frac{15}{11}$. Photons need to be sampled according to $(0.4 + 0.6\mu)\mu d\mu$.

In the code `pcyg.f90` this corresponds to `test_number = 3` (not yet implemented).

Via this link, you can go back to the exercises overview: Section 2.

### 4.3.5   Fourth adaptaion: photospheric line-profile

Challening: Put photospheric line-profile (simple Gaussian) in !What happens? Test on xk0=0 (opacity =0) case.

- test case number 4 (not yet implemented)

**4.3.6 Convergence analysis**

Figure 8: Original version of the code: convergence analysis (xk0=0)

Via this link, you can go back to the exercises overview: Section 2.

# 5 Milic Exercises

## 5.1 Lecture 7

1. Derive expressions for the emergent radiation when properties are the following:

   - optically thin slab at all wavelengths
   - wavelength-independent incident radiation

   Solution: see slide 14?

2. Derive ralations between Einstein coefficients.

3. Calculate electron density in atmosphere from FALC model

# 6   Mass loss from inhomogeneous hot star winds (Sundqvist)

- GOAL: synthesis of UV resonance lines from inhomogeneous 2D winds

  - clumped in density

  - clumped in velocity

  - effects of non-void inter-clump medium

- WIND MODELS

  - symmetry assumptions
    * 1D: spherical symmetry
    * 2D: symmetry in $\Phi$

  - models
    1. time-dependent radiation-hydrodynamic from Puls and Owocki (POF)
       * 1D
       * isothermal flow
       * perturbations triggered by photospheric sound waves
    2. time-dependent radiation-hydrodynamic from Feldmeier (FPP)
       * 1D
       * treatment of energy equation
       * perturbations triggered by photospeheric sound waves or Langevin perturbagions (photospheric turbulence)
    3. stochastic model, clumped in density
       * smooth winds with $v_\beta = (1 - b/r)^\beta$ with $\beta = 1$
       * clumping factor $f_{cl}$
    4. stochastic model, clumped in density and in velocity (non-monotonic velocity field)
       * smooth winds with $v_\beta = (1 - b/r)^\beta$ with $\beta = 1$
       * clumping factor $f_{cl}$

- RADIATIVE TRANSFER (MC-2D)

# 7 Asymptotic preserving Monte Carlo methods for radiative transfer equation in diffusion limit (Dimarco+ 2018)

## 7.1 Goldstein-Taylor

## 7.2 Radiative transfer
